

Parameter count does not determine compute

IMP and SNIP execute a flat 29.42M MACs at every level – the horizontal line at the top. DSP's packed-shape MACs track the base'channels dense family to within 4.2% at every level, which is the sense in which structured pruning recovers a real architecture rather than a mask; the bars on DSP are its min-max range over three seeds, up to 4.8% wide, because a DSP seed re-runs the filter grouping and therefore arrives at a different architecture.

The diagonal marks what proportional scaling would give; every dense point above it spends more compute per parameter than the baseline does, every point below it spends less.
